

Figure 1: WONDA pipeline on 2456_3.c. The raw verifier output (V_0) is normalized (V_1); the LLM then extracts the triangular-number closed form and keeps only necessary loop bounds (V_2): `sum == i * (i - 1) / 2 && i <= n && n <= 100 && 0 <= i`, a $481\times$ character reduction with $5.1\times$ verification speedup.
